

Agent Loop Diagram — Maker / Checker Refinement

Every loop obeys one law: the agent that makes an artifact never grades it. A separate checker with its own context and rubric holds the gate.

Maker agent Checker / verifier (separate) Artifact (versioned) Human gate ➡ pass ➔ advance ➡ fail ➔ loop back

LOOP 1 - CONTENT REFINEMENT (offline)

LOOP 2 - ENGINE INTEGRITY (guards the frozen core)

LOOP 3 - ORCHESTRATION (planner fans out work, gates each return)

isolated git worktrees per agent - verifier gates every artifact - orchestrator retries or escalates - CLAUDE.md accumulates lessons

Progressive refinement:

Artifacts are versioned. Each loop pass produces v_n+1 only if the checker accepts it; rejected drafts carry the verifier's specific defect list back to the maker. Bounded iterations (never infinite), a hard human backstop on the engine loop, and a shared verifier so quality is uniform across every maker in the swarm. The one inviolable rule: no maker ever sits in judgment of its own artifact. That single constraint is what keeps a self-improving system honest.
